(54) Production of synthetic plastics foam material.

(57) Polyurethane foam is formed by the reaction of a polyisocyanate with a polyol in the presence of water. The water reacts with the isocyanate to give carbon dioxide gas which causes the reaction mixture to foam.

The foaming is carried out under controlled conditions of pressure less or greater than atmospheric pressure.

PRODUCTION OF SYNTHETIC PLASTICS FOAM MATERIAL
TECHNICAL FIELD OF THE INVENTION

The invention concerns the production of synthetic plastics foam materials and has particular, though not
5. exclusive, reference to the production of polyurethane foam material in block form.

The world consumption of polyurethane foam is at a high level and is widely spread geographically. Accordingly, its manufacture is the subject of constant
10. studies in order to find new methods whereby its range of usage may be widened by obtaining new types of foam and at the same time reducing the cost.

BACKGROUND ART

The conventional methods of producing polyurethane
15. foam are mainly based on a mixture consisting basically of polyol, toluene diisocyanate (TDI), water, silicone, and various catalyst agents. The polyol reacts with a part of the TDI to produce polyurethane, whilst a part of the TDI reacts with water to give CO₂ and amines.
20. The amines, in their turn, react with another part of the TDI to produce urea. The CO₂ promotes foaming of the polyurethane, thereby determining its density, and the urea gives the hardness to the finished product. Silicone stabilizes the foam and regulates the size of
25. the foam cell, whilst the various catalysts speed up

(PCT13009)
(2.7.81)

- 2 -

the formation of gas and the gelling of the foamed mix.

In the conventional foam-making process both the mixing of the individual components and the resultant
5. chemical reactions take place at atmospheric pressure and at a temperature of approximately 22°C.

When it is required to produce very soft foam, it is known to add a fluorocarbon such as monofluoro-trichloromethane to the mix to increase the foam
10. volume without varying the amount of urea, thus reducing both the density and the hardness.

DISCLOSURE OF THE INVENTION

The primary object of the invention is to produce cheaper foams than has hitherto been possible, and,
15. furthermore, to extend the range of available foams by suitable selection of foam density and hardness.

According to the present invention there is proposed a method for the production of synthetic foamed plastics materials using formulations based on a polyol,
20. a polyisocyanate and a blowing agent, characterised by foaming under controlled conditions of pressure.

The polyol may comprise any suitable polyhydroxyl compound or combination of substances such as are conventionally used in the polyurethane process.

25. The polyisocyanate may also comprise any suitable substance or combination of substances especially the substance known as toluene diisocyanate (TDI).

Most preferably the presence of water is relied upon to provide the blowing agent, such water reacting
30. with the isocyanate to give carbon dioxide gas as described above, and this may constitute the only blowing agent. Alternatively or additionally however other blowing agents may be used including volatile organic compounds such as fluorocarbons.

35. Other substances as conventionally used in the

(PCT13009)
(2.7.81)

- 3 -

polyurethane process, such as silicone and catalysts (e.g. amine and/or organometallic catalysts) may be incorporated as desired and as appropriate.

The process may be operated at conventional

5. temperature levels and using conventional apparatus or otherwise as desirable and as suitable. In a particularly preferred embodiment the process is operated in a closed-circuit system.

- With the method of the invention, when foams are
10. made under pressures greater than atmospheric, under certain conditions, the cells can be completely open due to bursting and due to implosion when the foam is produced under a pressure lower than atmospheric, that is to say when the pressure difference between the
15. inside and outside of the cell is such as to break the cellular membrane.

- In conditions of reduced pressure, relative to atmospheric pressure at which foaming occurs with the conventional process, the volume of CO₂ produced from
20. a standard formulation of the kind described above increases to increase the degree of foaming and give a product of considerably greater volume. The resultant foam is, however, much softer than foam of the same density produced under normal conditions of
25. pressure.

- If it is required to produce a foam of normal characteristics as regards density and hardness, the increased volume of CO₂ resulting from the lower process pressure reduces the consumption of CO₂ and
30. consequently of water and TDI, such reductions having a favourable effect on production costs.

- An operating pressure in excess of atmospheric pressure has the effect of reducing the volume of CO₂ produced, and accordingly more water and TDI will be
35. required to generate a quantity of CO₂ (or other gas)

(PCT13009)
(2.7.81)

- 4 -

appropriate to the production of a foam having a density similar to that produced by a conventional process operated at atmospheric pressure. However, the increased amount of water leads to an increase in the amount of amines, and this increase, in its turn, increases the amount of urea and gives a foam of increased hardness.

EXAMPLES OF THE BEST MODE FOR CARRYING OUT THE INVENTION

The invention will now be described further, by way of example only, and with reference to the following Examples 1 to 5 in which Examples 2 and 5 are examples of the process of the invention whereas Examples 1, 3 and 4 are comparative examples of processes not in accordance with the invention.

15. EXAMPLE 1

A flexible polyurethane foam is prepared using the following formulation in a machine having four jets in the mixing head and operating at 4000 r.p.m.

	<u>Parts by weight</u>
20. Polypropyleneglycol molecular weight 4200	100
Toluene diisocyanate 80/20	49.97
Water	4.00
Dimethylethanol amine	0.35
25. Silicone Oil	1.00
Tin Octoate	0.25
Diethylphthalate	2.50

The materials are introduced through the respective jets into the mixing chamber in accordance with the following scheme:-

(PCT13009)
(2.7.81)

- 5 -

	<u>Material</u>	<u>Rate of Flow</u>
Jet 1	Polypropyleneglycol	60 kg/min.
Jet 2	Toluene diisocyanate	29.38 kg/min
Jet 3	Mixture of water, dimethylethanol amine, amine and silicone oil	3.210 kg/min.
5. Jet 4	Balance of materials	1.650 kg/min.

After mixing for several seconds the mixture is led to a 100 x 100 x 100 cm mould at atmospheric pressure (710mm Hg gauge). The resultant foam had a density of 24.5 kg/m³.

EXAMPLE 2

The formulation of Example 1 is delivered to the mixing head under like flow conditions, is led to a mould of similar dimensions after having been mixed for ten seconds and is allowed to foam in a reduced pressure environment (350mm Hg gauge). The resultant foam has a density of 14.1 kg/m³.

EXAMPLE 3

The following formulation was used to produce a foam of like density to that set forth in Example 2, the process being operated at atmospheric pressure, (710mm Hg gauge).

	Polypropyleneglycol	100.
	Toluene diisocyanate	59.12
25. Water		5.00
	Dimethylethanol amine	0.35
	Silicone Oil	1.00
	Tin Octoate	0.25
	Dioctylphthalate	2.50
30. Monofluorotrichloromethane		15.00

It is to be observed that an increased amount of toluene diisocyanate is required, and this increase, together with the additional fifteen parts of monofluorotrichloromethane for every hundred parts of polyol, significantly increases the cost of the foam in relation

(PCT13009)
(2.7.81)

- 6 -

to that produced in accordance with Example 2.

EXAMPLE 4

A foam was prepared under normal atmospheric pressure conditions, using the following formulation:

5. Polypropyleneglycol	100.
Toluene diisocyanate	34.76
Water	2.60
Dimethylethanol amine	0.50
Silicone Oil	0.80
10. Tin Octoate	0.20
Diethylphthalate	2.00

The resultant foam had a density of 34.2 kg/m^3 , and an indentation hardness of 15.9 kg to UNE Standard 14. ✓

15. EXAMPLE 5

The formulation of Example 1 is delivered to the mixing head under like conditions and a foam of a density of 34.1 kg/m^3 is obtained by foaming in a pressure chamber at 1 kg/cm^2 pressure. The indentation hardness of this foam was 60 kg to UNE Standard 14.

Operation of the process as hereinproposed in a closed-circuit system provides the great advantage, as far as the operators are concerned, that the gases released during the process can readily be contained, and thus the operators are not under any risk. Additionally, monofluorotrichloromethane gases, on release, may easily be collected and compressed for subsequent recovery. Furthermore, in the context of a closed-circuit system an increased amount of monofluorotrichloromethane may be used, thereby reducing the TDI requirement, without increasing the manufacturing cost of the foam, since the monofluorotrichloromethane is recoverable.

(PCT13009)
(10.7.81)

- 7 -

INDUSTRIAL APPLICABILITY

The process as hereinproposed allows of the production at a lower price of softer foams of like density, or of foams of characteristics similar to

5. those of foams produced by conventional methods, simply by reducing the pressure at which the foaming takes place. Alternatively, foams of similar density but higher hardness than foams produced at atmospheric pressure may be produced simply by increasing the
10. pressure at which the foaming takes place.

The invention is of particular application to the production of foam in block or moulded form, especially large blocks having dimensions of the order of two metres by one metre by one metre.

15. It has been found that the density change brought about by the affect of reduced or increased pressure is of the order of about 3 kg/m^3 for each 100mm by which the maintained pressure falls below or exceeds the prevailing atmospheric pressure. The actual
20. pressure selected will depend on the nature of the foam required.

- For a low density foam the pressure will be reduced (by at least say 50mm corresponding to $1\frac{1}{2} \text{ kg/m}^3$ density reduction, and preferably more up to say 650mm)
25. so that the foam expands well without need for incorporation of high proportions of organic blowing agent.

- For a high density foam, the pressure will be increased (again by at least 50mm corresponding to $1\frac{1}{2} \text{ kg/m}^3$ density increase, and preferably more up to say 4 kg/cm^2)
30. and expansion of the foam is restrained. With the conventional foaming procedure, water content in the reaction mixture gives rise to the production of hardening urea groups but the hardening effect is offset by the expansion of the foam (by the carbon
 35. dioxide produced by reaction of the water with the

(PCT13009)
(7.7.81)

- 8 -

- isocyanate) which disperses the urea groups and diminishes the effect thereof. With the increased pressure process of the present invention, sufficient water can be incorporated to give a desired level of
5. urea group production without this giving rise to undue foam expansion. Accordingly such process permits of the formation of foams which are relatively hard yet which are flexible and may have conventional densities, it being understood that increased hardness
10. in a flexible foam may be desirable, particularly for example for furniture applications, in so far as such foams give good support. In general it will be appreciated that the present invention gives greater freedom for the production of foams of desired
15. density and hardness by appropriate selection of the pressure and chemical formulation.

- The process of the invention may be performed using a conventional mixing head which acts to mix the ingredients of the reaction mixture and then feeds
20. same to a cylindrical chamber in communication with the bottom of a reaction vessel in the form of a large rectangular open-topped box, such chamber having therein a piston movable within the chamber to sweep the contents thereof out of the chamber into the bottom of the box.
25. With the conventional process the reaction mixture would be allowed to foam and expand within the box whilst this is open to the atmosphere. In accordance with the present invention, however, such box is enclosed as for example by application of a lid to the
30. top of same or by insertion of the box bodily into an outer closable chamber and the pressure conditions within the box are controlled whilst the reaction mixture reacts and expands. Where high pressure conditions are required it may be sufficient simply to
35. rely on the increase in pressure on sealing of the box

(PCT13009)
(7.7.81)

- 9 -

- caused by rising of the foam and also the evolution of gaseous products such as carbon dioxide, isocyanate fumes, organic vapours. Indeed where a substantially constant high pressure is to be maintained it may be
5. necessary to provide a relief valve in communication with the box which allows release of air and gaseous products when the pressure exceeds the predetermined constant value. Alternatively or additionally and as appropriate the box may be connected to a compression
10. pump and this may be operated in conjunction with a pressure gauge, relief valve, switching controls as appropriate to maintain a desired pressure. Where a low pressure is required the box may be connected to a vacuum pump and appropriate controls and auxiliary
15. equipment may be provided to enable a substantially constant reduced pressure to be maintained. Appropriate recovery apparatus may be interposed between the vacuum pump and the box where organic blowing agent or other substances are to be recovered.
20. The reaction mixture is maintained in the enclosed box until such mixture has gelled and the foam has reached approximately a maximum height this being determined on a pre-assessed time basis or alternatively by monitoring the reaction via a sight glass and/or
25. with appropriate sensor equipment.
- The pressure is then returned to atmospheric and the box is opened or removed from the enclosing chamber to enable the resulting block of foam to be removed from the box.
30. It is also possible to operate the process of the invention on a continuous basis, for example, by discharging the reaction mixture to a conveyor belt running within a chamber which is enclosed and maintains required pressure conditions around the belt as the mixture reacts
35. and foams thereon.

(PCT13009)
(13.7.81)

- 10 -

Where the process is operated at reduced pressure in the presence of fluorocarbon 11 the pressure reduction permits a fluorocarbon saving (in parts per 100 parts polyol) as follows:

5.	<u>Pressure reduction (mm Hg)</u>	<u>Saving</u>
	50	2.5
	100	6
	200	13
	300	23
10.	400	35

(PCT13009)
(7.7.81)

- 11 -

Claims:

1. A method for the production of synthetic foamed plastics materials using a reaction mixture based on a polyol, a polyisocyanate and a blowing agent,
5. characterised by foaming under controlled conditions of pressure.
2. A method according to claim 1, characterised in that the process is operated at substantially constant pressure which differs from the prevailing atmospheric
10. pressure.
3. A method according to claim 1 or 2, characterised in that the process is operated in a reaction chamber which is connected to a vacuum pump which operates to maintain the pressure in the chamber below prevailing
15. atmospheric pressure.
4. A method according to claim 1 or 2, characterised in that the process is operated in a reaction chamber in which the pressure rises above prevailing atmospheric pressure due to foaming of and production of gases by
20. the reaction mixture.
5. A method according to claim 4, characterised in that the chamber is also pressurised by the action of a compression pump connected to the chamber.
6. A method according to any one of claims 1 to 5,
25. characterised by the performance of the following steps:
the reaction mixture is introduced into a reaction chamber before completion of foaming thereof;
the said reaction chamber is enclosed;
the pressure within the enclosed chamber is controlled
30. whilst the reaction mixture foams;
the reaction chamber is opened and the foamed mixture is removed from same.
7. A method according to any one of claims 1 to 6, wherein water is utilised to provide the said blowing
35. agent, characterised in that said water reacts with

(PCT13009)
(7.7.81)

- 12 -

the polyisocyanate to produce carbon dioxide under said conditions of controlled pressure.

8. A method according to any one of claims 1 to 7, characterised in that the reaction mixture also
5. contains a volatile organic substance as a blowing agent, characterised in that the process is operated under closed-circuit conditions and evolved said organic substance is recovered from exhaust gases of the process.
10. 9. A method according to any one of claims 1 to 8, characterised in that the said reaction mixture includes one or more of silicone, an amine catalyst, an organometallic catalyst.
10. Polyurethane foam material when made by the
15. method of any one of claims 1 to 9.
